Example Model: Auxiliary Variables

Constants & Time Series Parameters

- For similar reasons to auxiliary variables, we give names to
 - Model constants
 - Time series

Example Model: Parameters

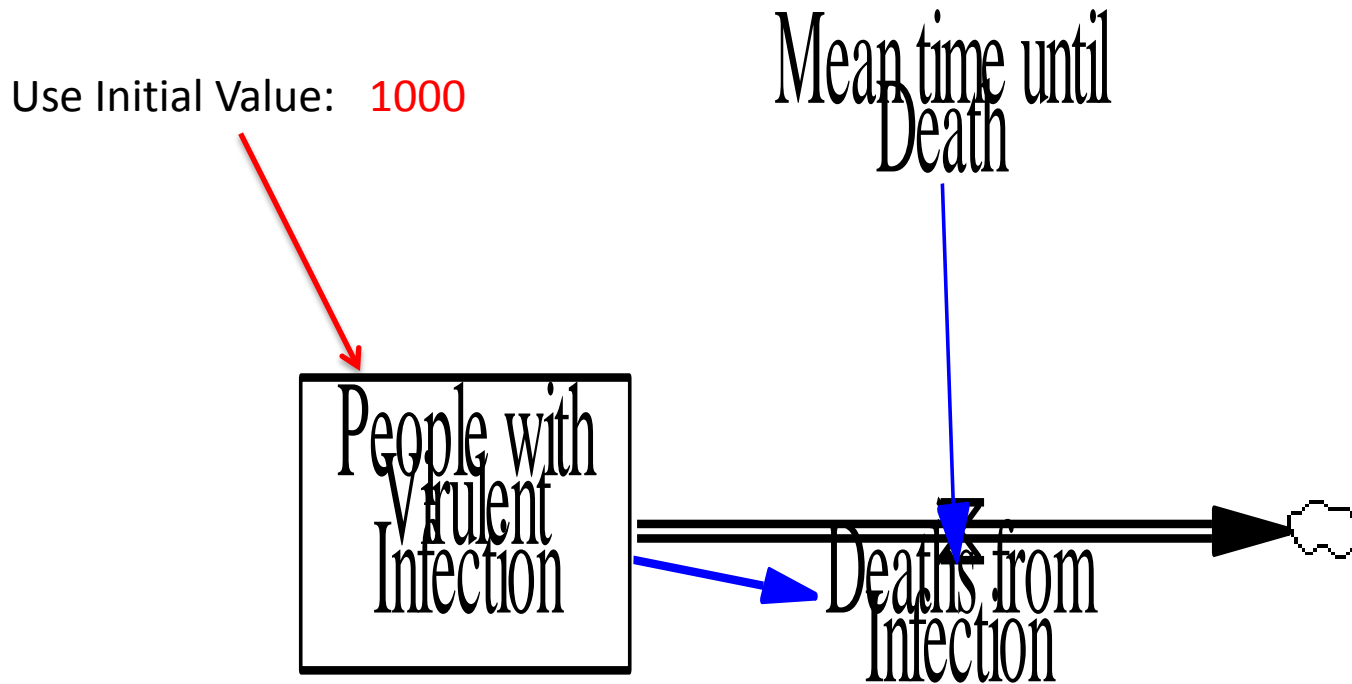

Example System Structure Diagram

Note treatment of flows as links from flow to stock

- Inflows as positive links
- Outflows as negative links

Simple First-Order Decay

Use Formula: $\text{Deaths from Infection} / \text{Mean time until Death}$

Set Model Settings (Model Menu/Settings Item)

Model Settings - use Sketch to set initial causes

Time Bounds | Info/Pswd | Sketch | Units Equiv | XLS Files | Ref Modes

Time Bounds for Model

INITIAL TIME = 0

FINAL TIME = 5

TIME STEP = 0.03125

Save results every TIME STEP

or use SAVEPER =

Units for Time Month

NOTE: To change later use Model>Settings or edit the equations for the above parameters.

Dynamics of Stock?

Dynamics of (Rate of) Death Flow?

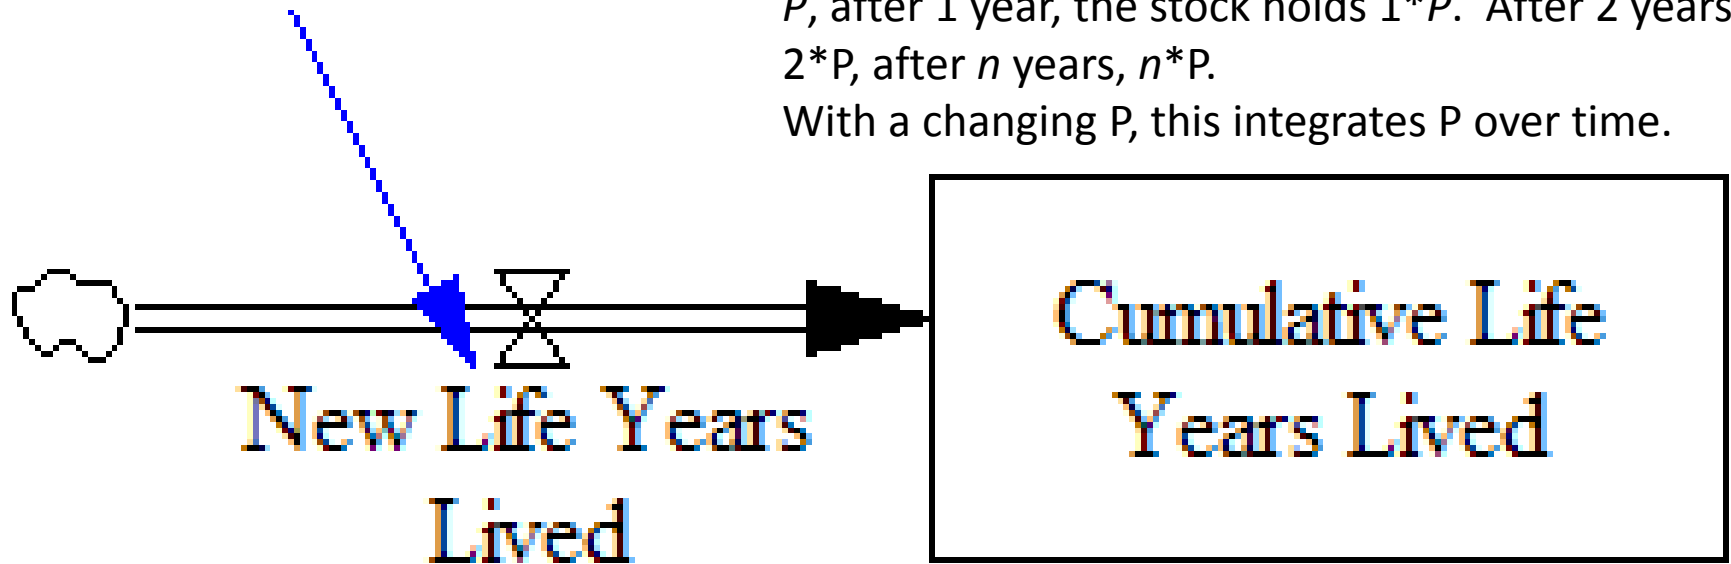

Stocks As Accumulations

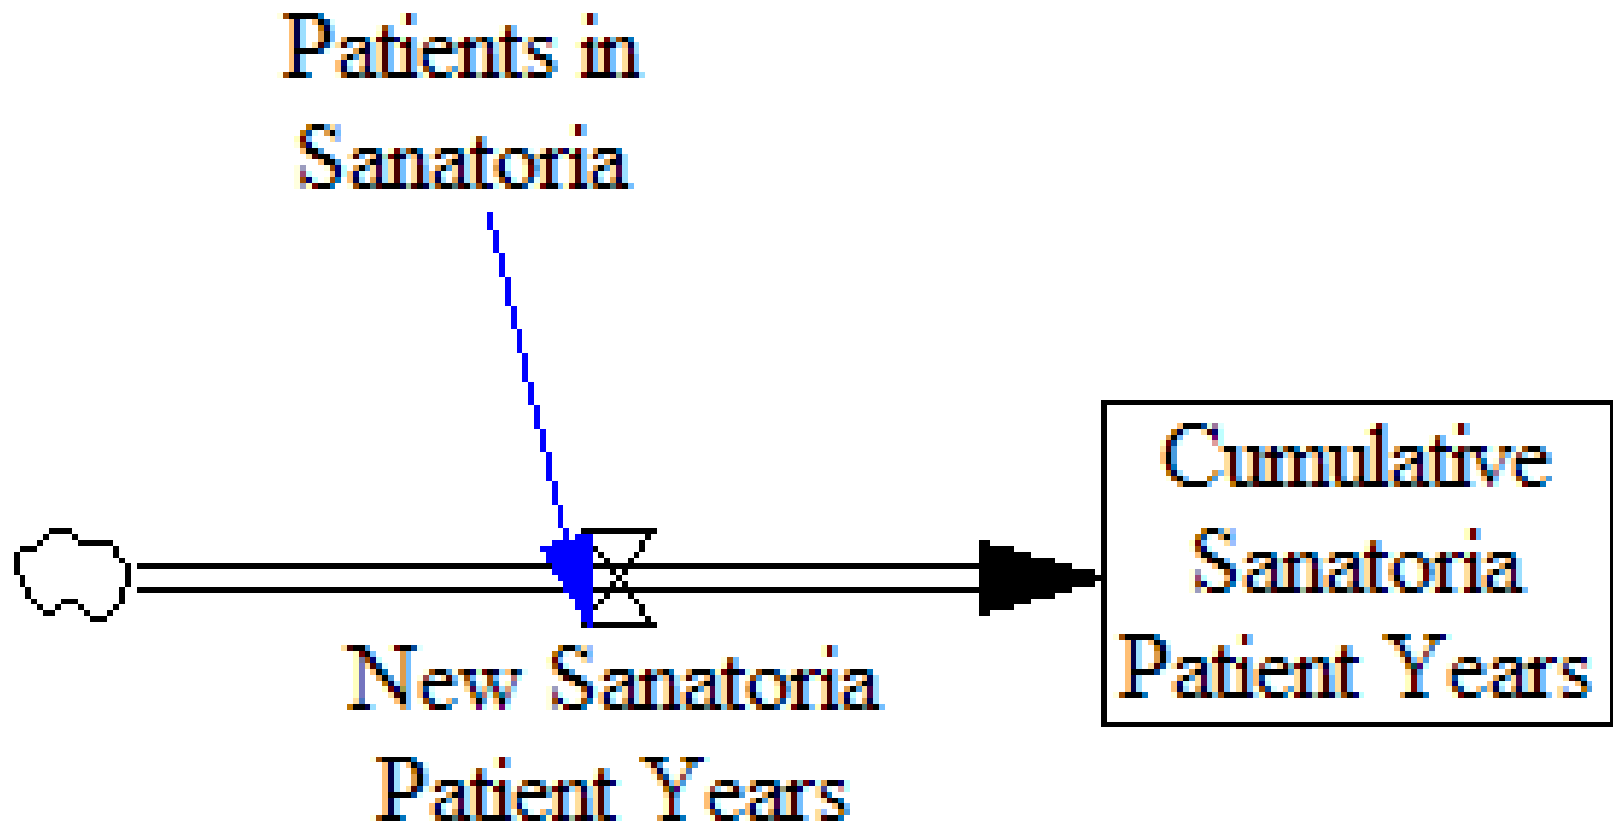

- We often use stocks to accumulate (integrate) other (evolving) quantities over time
- Example (assume time measured in years):

Current Population

A Key Reflection: If we have population of size P , after 1 year, the stock holds $1 * P$. After 2 years, $2 * P$, after n years, $n * P$.
With a changing P , this integrates P over time.

Another Example of Stocks as Accumulations

Slightly more Sophisticated

Principle: Structure Determines Behaviour

- Feedback & stock-and-flow structure of a system determines the possible patterns of behaviour
- Different sets of parameters (e.g. values for constants) will select particular behaviour within these behaviour patterns
- Changes to the feedback structure can change behaviour in fundamental ways

Simple SIT Model

Broadening the Model Boundaries: Endogenous Recovery Delay

Broadening the Model Boundaries: Endogenous Recovery Delay

A Different Behaviour Mode

Prevalence, Infectious

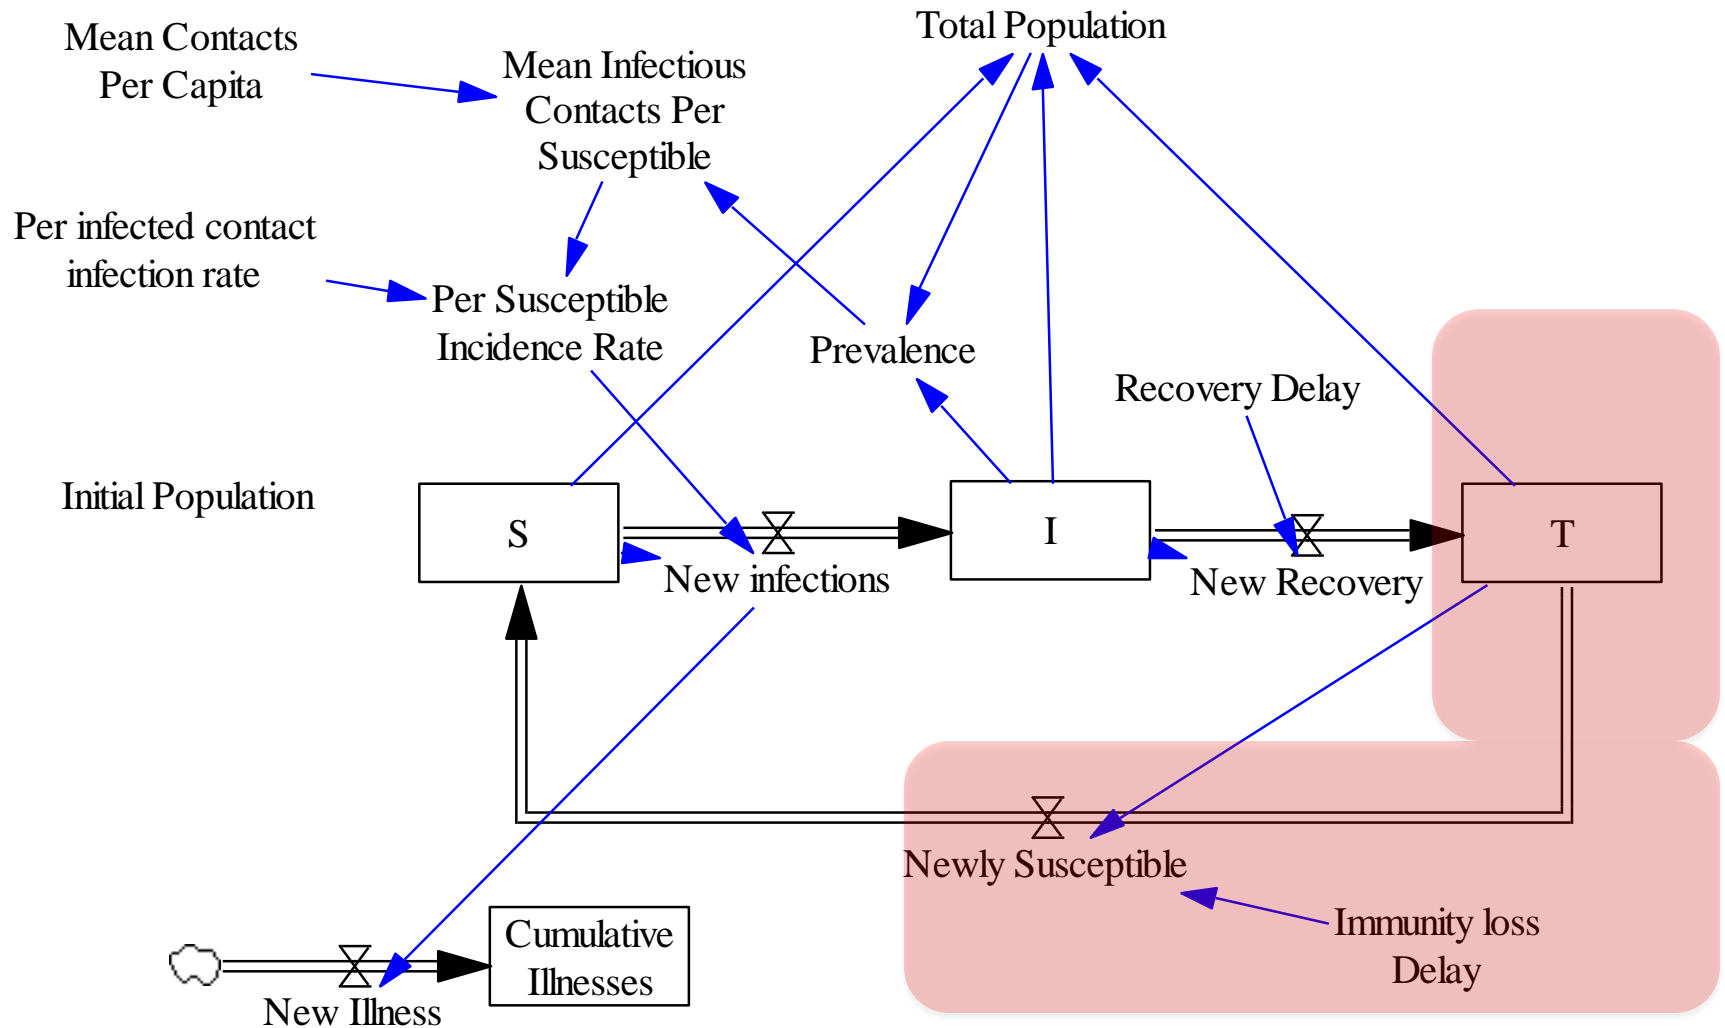

Prevalence : Baseline 30 HC Workers ————— 1
I : Baseline 30 HC Workers ————— Person

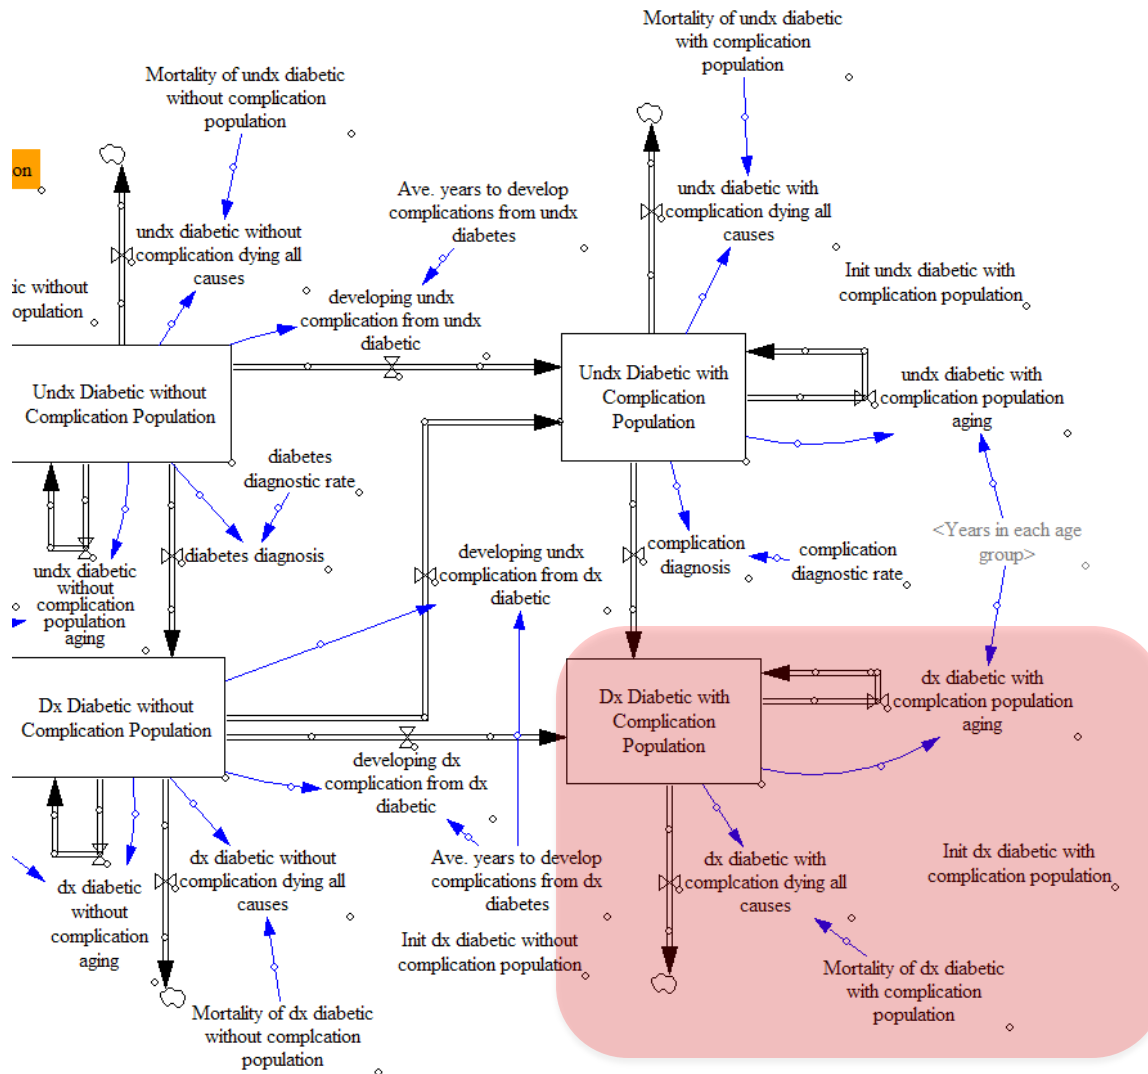

Structure as Shaping Behaviour

- System structure is defined by
 - Stocks
 - Flows
 - Connections between them
- Nonlinearity: The behaviour of the whole is more than the sum of the behaviour of the parts
 - “Emergent” behaviour would not be anticipated from simple behaviour of each piece in turn
- Stock and flow structure (including feedbacks) of a system determines the qualitative behaviour modes that the system can take on

First Order Delays in Action: Simple SIT Model

First Order Delays in Action: Simple SIT Model

Scenarios for First Order Delay: Variation in Inflow Rates

- For different immigration (inflows) (what do you expect?)
 - Inflow=10
 - Inflow=20
 - Inflow=50
 - Inflow=100
 - Why do you see this “goal seeking” pattern?
 - What is the “goal” being sought?

Behaviour of Stock for Different Inflows

People (x)

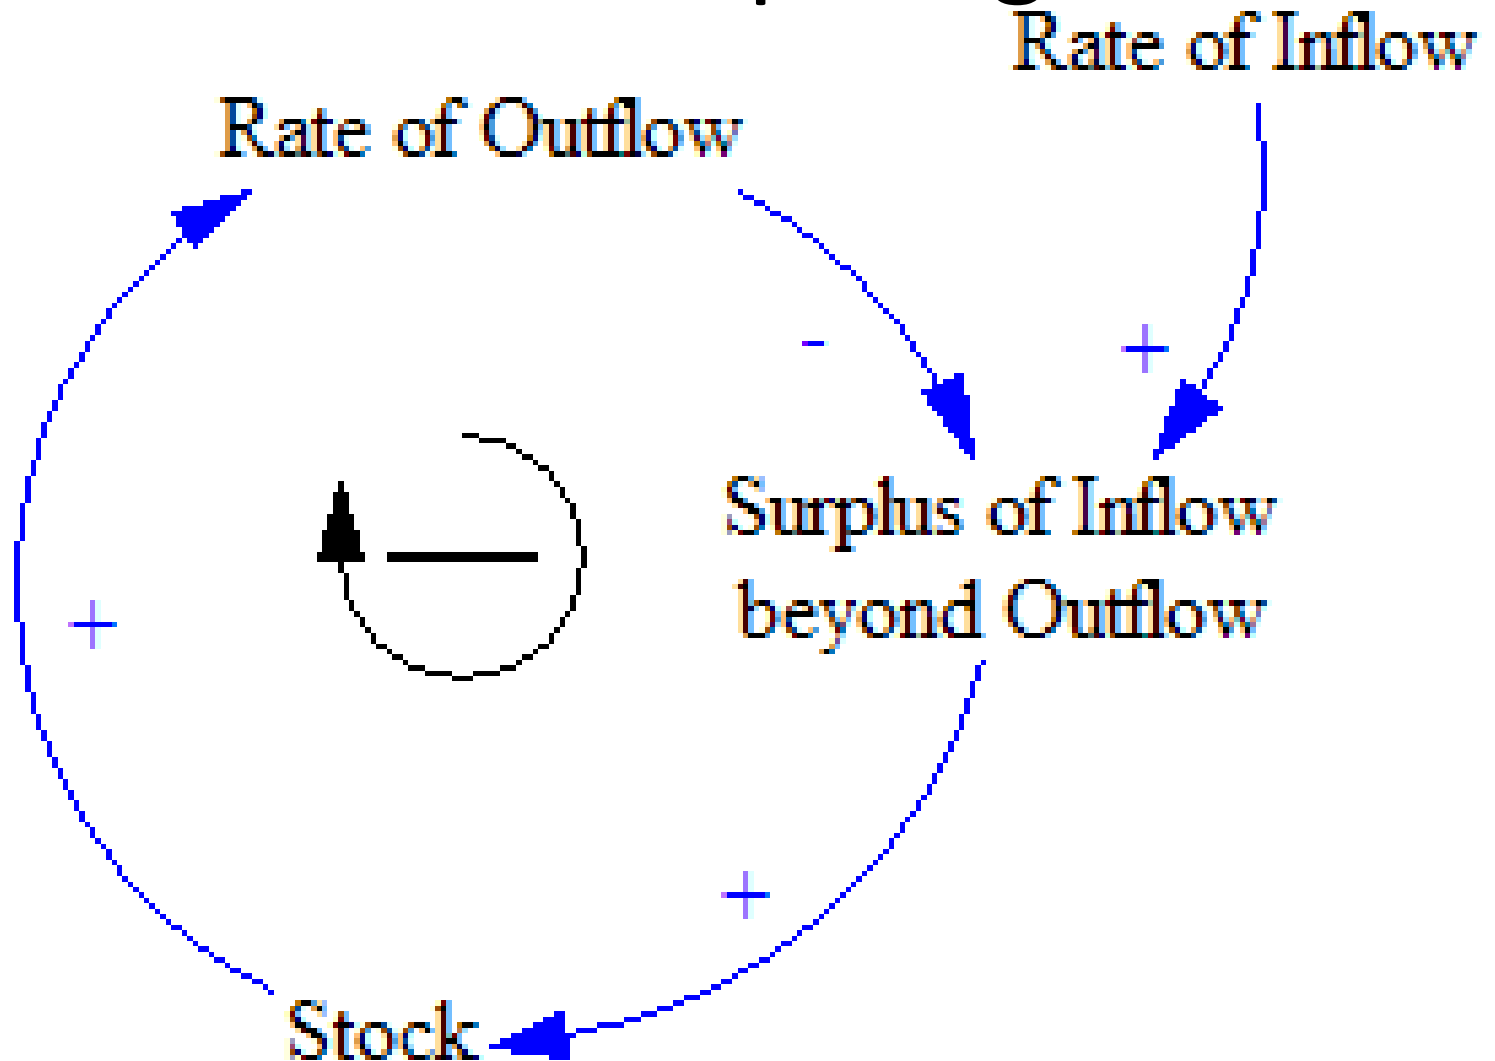

- "People (x)" : Alternative Inflow=100
- "People (x)" : Alternative Inflow=50
- "People (x)" : Alternative Inflow=20
- "People (x)" : Alternative Inflow=10
- "People (x)" : Alternative Inflow=0

Why do we see this behaviour?

Goal Seeking Behaviour

- The goal seeking behaviour is associated with a negative feedback loop
 - The larger the population in the stock, the more people die per year
- If we have more people coming in than are going out per year, the stock (and, hence, outflow!) rises until the point where inflow=outflows
- If we have fewer people coming in than are going out per year, the stock declines (& outflow) declines until the point where inflow=outflows

As a Causal Loop Diagram

What does this tell us about how the system would respond to a sudden change in immigration?

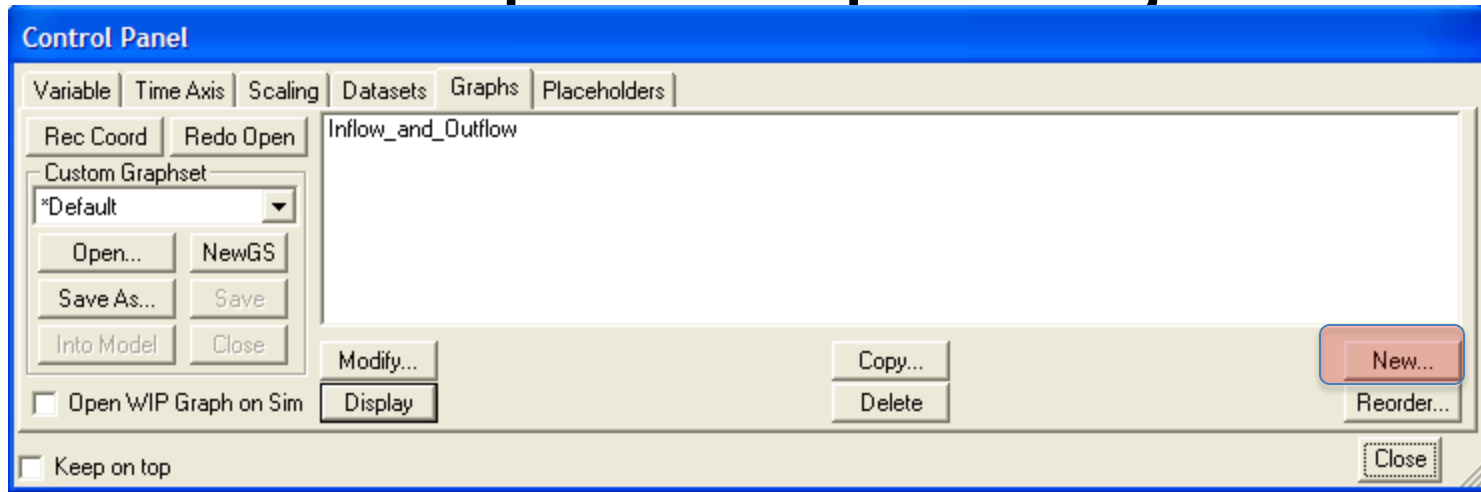

Response to a Change

- Feed in an immigration “step function” that rises suddenly from 0 to 20 at time 50

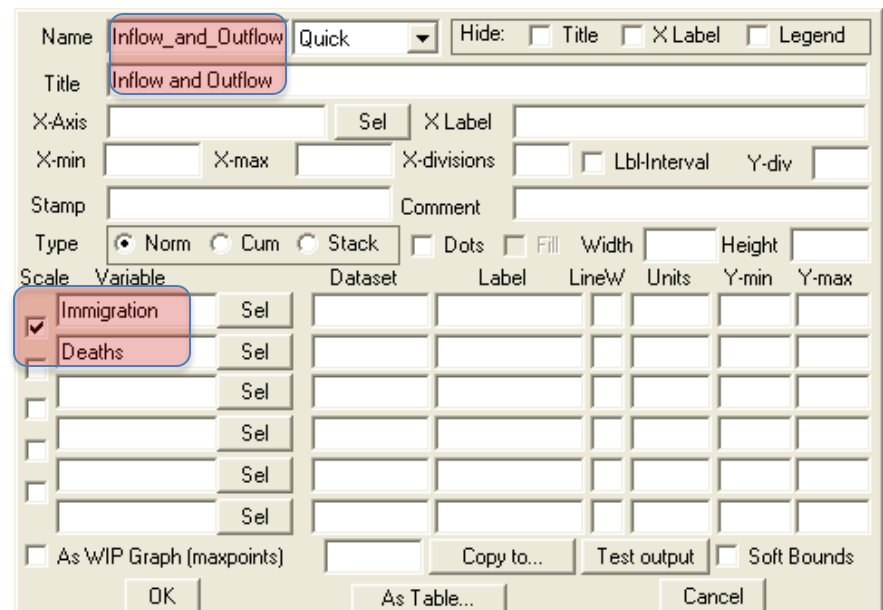

- Set the Initial Value of Stock to 0
- How does the stock change over time?

Create a Custom Graph & Display it as an Input-Output Object

- Editing

Create Input-Output Object (for Synthesim)

Input Output Object settings

Object Type

Custom Graph or Analysis Tool for Output

Stock Starting Empty

Flow Rates Inflow and Outflow

Immigration : Step Function 0 to 20 Initial Stock Empty
Deaths : Step Function 0 to 20 Initial Stock Empty

How would this change with alpha?

Stock Starting Empty?

Value of *Stock* (Alpha=.05)

People (x)

"People (x)" : Step Function 0 to 20 Initial Stock Empty

How would this change with alpha?

For Different Values of $(1/\alpha)$ Alpha Flow Rates (Outflow Rises until = Inflow)

Deaths

Deaths : Step Functions 2 yr delay —————

Deaths : Step Functions 20 yr delay —————

Deaths : Step Functions 10 yr delay —————

Deaths : Step Functions 5 yr delay —————

This is for the *flows*. What do stocks do?

For Different Values of (1/) Alpha Value of Stocks

"People (x)" : Step Functions 2 yr delay

"People (x)" : Step Functions 20 yr delay

"People (x)" : Step Functions 10 yr delay

"People (x)" : Step Functions 5 yr delay

Why do we see this behaviour? A longer time delay (or smaller chance of leaving per unit time) requires x to be *larger* to make outflow=inflow

Outflows as Delayed Version of Inputs

Inflow and Outflow

Immigration : Step Functions 2 yr delay —————
 Deaths : Step Functions 2 yr delay —————

Inflow and Outflow

Immigration : Step Functions 10 yr delay —————
 Deaths : Step Functions 10 yr delay —————

Inflow and Outflow

Immigration : Step Functions 5 yr delay —————
 Deaths : Step Functions 5 yr delay —————

Inflow and Outflow

Immigration : Step Functions 10 yr delay —————
 Deaths : Step Functions 10 yr delay —————

Higher Order Delays & Aging Chains

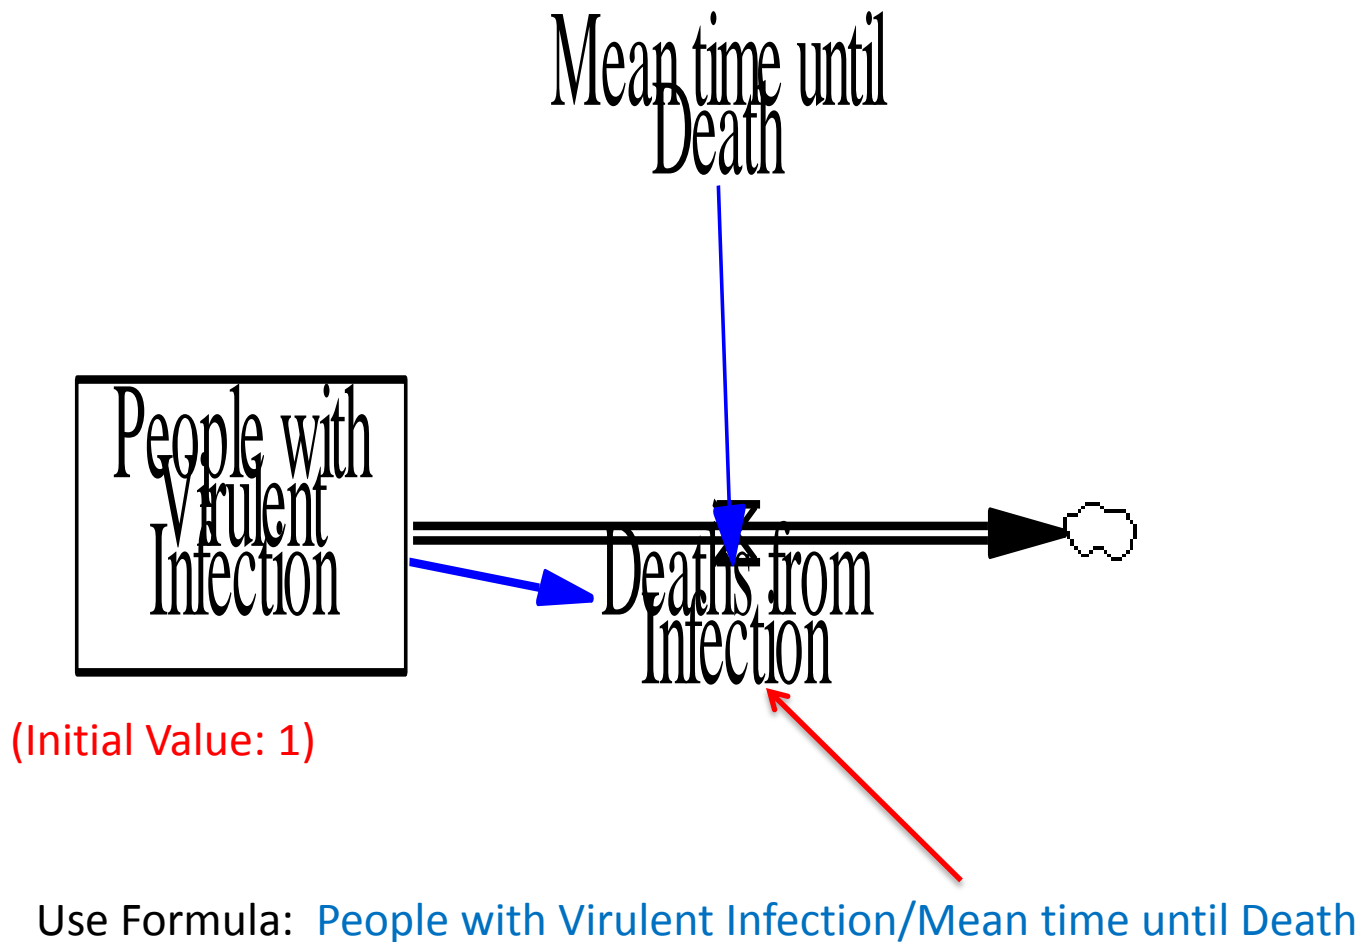

Moving Beyond the “memoryless assumption”

- Recall that first order delays assume that the per-time-unit risk of transitions to the outflow remains equal throughout simulation (i.e. are memoryless)
- Problem: Often we know that transitions are *not* “memoryless” e.g.
 - It may be the transition reflects some physical delays not endogeneously represented (e.g. Slow-growth of bacterial)
 - Buildup of “damage” of high blood sugars (Glycosylation)

Higher Orders of Delays

- We can capture different levels of delay (with increasing levels of fidelity) using cascaded series of 1st order delays
- We call the delay resulting from such a series of k 1st order delays a “ k^{th} order delay”
 - E.g. 2 first order delays in series yield a 2nd order delay
- The behaviour of a k^{th} order delay is a reflection of the behaviour of the 1st order delays out of which it is built
- To understand the behaviour of k^{th} order delays, we will keep constant the mean time taken to transition across the entire set of all delays

Recall: Simple 1st Order Decay

Recall: 1st Order Delay Behaviour

- **Conditional** transition prob: For a 1st Order delay, the per-time-unit likelihood of leaving *given that one has not yet left the stock* remains constant
- **Unconditional** transition prob: For a 1st Order delay, the unconditional per-time-unit likelihood of leaving declines exponentially
 - i.e. if we were originally in the stock, our chance of having left in the course of a given time unit (e.g. month) declines exponentially
 - This reflects the fact that there are fewer people who could still leave during this time unit!

Recall: 1st Order Delay Behaviour

Stage 1 Outflow

Stage 1

1st Order Delay (Per-month chance of transitioning out during this month)

(Likelihood of Still being In System)

2nd Order Delay

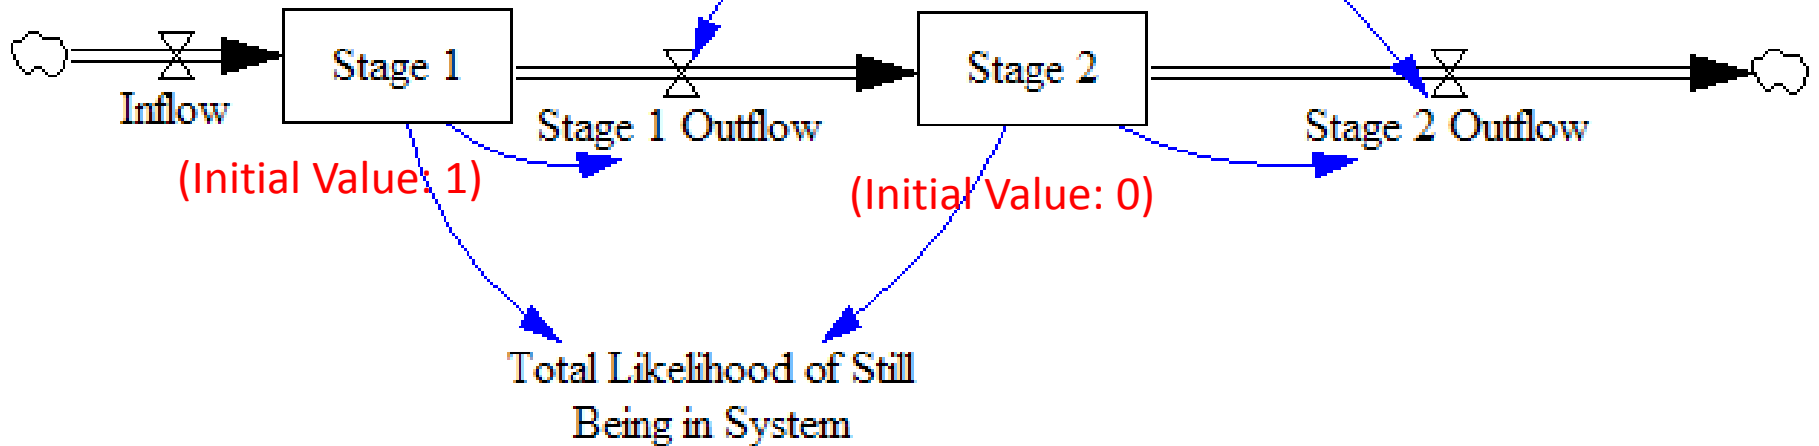

Use Formula:

Mean Time to Transition Across All Stages/Stage Count

Mean Time to Transition Across All Stages
(Use value of 50)

Stage Count
(Use value of 2)

Mean Time to Transition Across Single Stage

2nd Order Delay

Stage 2 Outflow

Total Likelihood of Still Beir

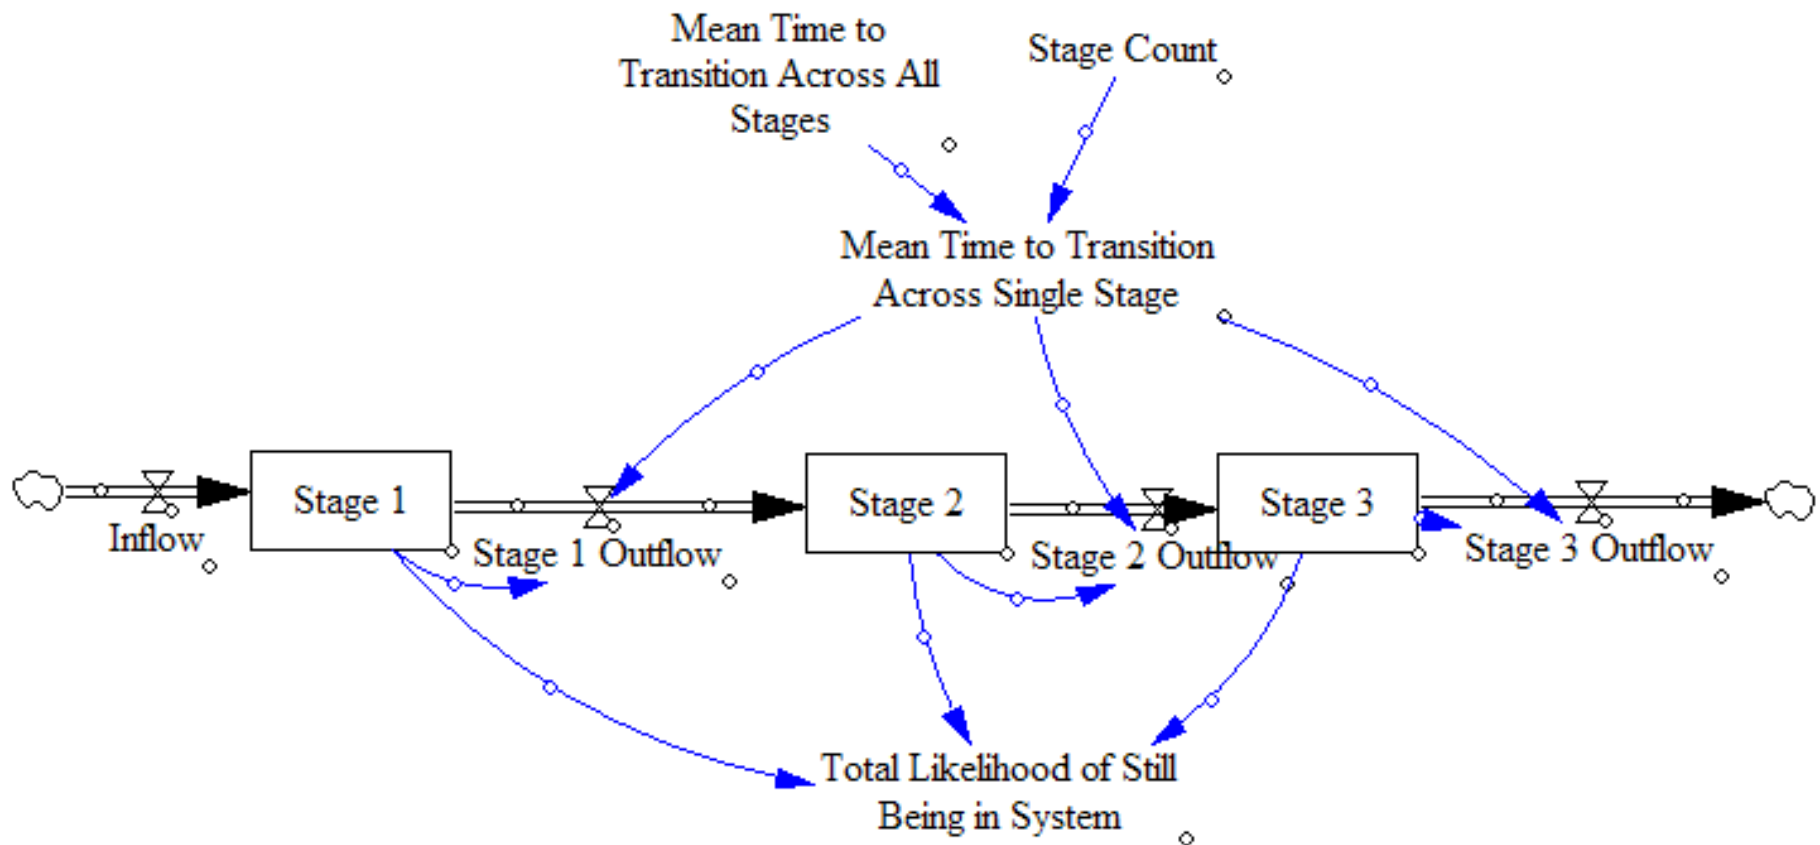

Stage 2 Outflow : 2nd Order Delay

(Per-month chance of transitioning out during this month)

(Likelihood of Still being In System)

3rd Order Delay

3rd Order Delay

Stage 3 Outflow

Total Likelihood of Still Being in

Stage 3 Outflow : 3rd Order Delay

(Per-month chance of transitioning out during this month)

(Likelihood of Still being In System)

1st through 6th Order Delays

- Outflow : 6th Order Delay For Comparison
- Outflow : 5th Order Delay For Comparison
- Outflow : 4th Order Delay For Comparison
- Outflow : 3rd Order Delay For Comparison
- Outflow : 2nd Order Delay For Comparison
- Outflow : 1st Order Delay For Comparison

Total Likelihood of Still Being in System

(Likelihood of Still being In System)

(Per-month chance of transitioning out during this month)

- Total Likelihood of Still Being in System : 6th Order Delay For Comparison
- Total Likelihood of Still Being in System : 5th Order Delay For Comparison
- Total Likelihood of Still Being in System : 4th Order Delay For Comparison
- Total Likelihood of Still Being in System : 3rd Order Delay For Comparison
- Total Likelihood of Still Being in System : 2nd Order Delay For Comparison
- Total Likelihood of Still Being in System : 1st Order Delay For Comparison

Mean Times to Depart Final Stage

- Mean time of k stages is just k times mean time of one stage (e.g. if the mean time for leaving 1 stage requires time μ , mean time for $k = k * \mu$)
- In our examples, as we added stages, we reduced the mean time per stage so as to keep the total constant!
 - i.e. if we have k stages, the mean time to leave each stage is $1/k$ times what it would be with just 1 stage
- Infinite order delay: As we add more and more stages ($k \rightarrow \infty$), the distribution of time to leave the last stage approaches a normal distribution
 - If we reduce the mean time per stage so as to keep the total time constant, this will approach an impulse function
 - This indicates an exactly fixed time to transition through all stages!

Distribution of Time to Depart Final Stage

- The distributions for the total time taken to transition out of the last of k stages are members of the *Erlang* distribution family
 - These are the same as the distribution for the k^{th} interarrival time of a Poisson process
- $k=1$ gives exponential distribution (first order delay)
- As $k \rightarrow \infty$, approaches normal distribution (Gaussian pdf)

Parameters	$k > 0 \in \mathbb{Z}$ shape $\lambda > 0$ rate (real) alt.: $\theta = 1/\lambda > 0$ scale (real)
Support	$x \in [0; \infty)$
Probability density function (pdf)	$\frac{\lambda^k x^{k-1} e^{-\lambda x}}{(k-1)!}$
Cumulative distribution function (cdf)	$\frac{\gamma(k, \lambda x)}{(k-1)!} = 1 - \sum_{n=0}^{k-1} e^{-\lambda x} (\lambda x)^n / n!$
Mean	k/λ
Median	no simple closed form
Mode	$(k-1)/\lambda$ for $k \geq 1$
Variance	k/λ^2
Skewness	$\frac{2}{\sqrt{k}}$
Excess kurtosis	$\frac{6}{k}$
Entropy	$(1-k)\psi(k) + \ln \frac{\Gamma(k)}{\lambda} + k$
Moment-generating function (mgf)	$(1-t/\lambda)^{-k}$ for $t < \lambda$
Characteristic function	$(1-it/\lambda)^{-k}$

“Aging Chains” (including successive 1st Order Delays & Competing Risks) in our Model of Chronic Kidney Disease
